1.7 Built in units of measure

Coordinates have many different types of unit e.g. latitudes are angles, but eastings are lengths.

There are also many different units in use across the world and across history, for instance most current mapping uses the metre for lengths, but older mapping often used feet or yards.

To avoid confusion about what any given number is intended to represent, all units in PHPCoord are typed as value objects.

Tip: All unit objects have helper methods `->getValue()` and `->getUnitName()`, and implement the `Stringable` interface

---

1.7.1 Units of angle

Tip: All angle units have helper methods `->asDegrees()`, `->asRadians()`, `->add()`, `->subtract()`, `->multiply()` and `->divide()`

Tip: You can access the list of supported angle units at runtime using `Angle::getSupportedSRIDs()` or `Angle::getSupportedSRIDsWithHelp()`

Degree

```
new Degree(float $angle)
Angle::makeUnit(float $angle, Angle::EPSG_DEGREE)
Angle::makeUnit(float $angle, 'urn:ogc:def:uom:EPSG::9102')
```

$\frac{}{180}$ radians

Tip: Degrees have a very large number of written representations. Although the *output* of PHPCoord will always be in decimal degrees, *input* helpers exist for many alternate representations.
